

# JavaScript Functions

---

.NET CORE

*JavaScript (JS) is a programming language that conforms to the ECMAScript specification.  
JavaScript is a high-level language that is often just-in-time compiled.*

[HTTPS://EN.WIKIPEDIA.ORG/WIKI/JAVASCRIPT](https://en.wikipedia.org/wiki/JavaScript)

# Create Sample .HTML and .js docs

---

Create a .html doc and save the below inside. It can be used to experiment with the examples in the presentation. The .js file and the .html file must be in the same folder.

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-
width, initial-scale=1.0">
  <meta http-equiv="X-UA-Compatible" content="ie=edge">
  <title>JS Example Document</title>
</head>
<body>
  <script src="pathToJSDoc.js"></script>
</body>
</html>
```

# JavaScript – Function Declarations

<https://javascript.info/function-basics>

---

JS functions can declare local variables and access those variables within the same scope. A local variable declared with the same name ***shadows*** the outer variable.

Variables are passed by value in JS.

A function with multiple ***parameters*** can be called with fewer ***arguments*** than parameters. The unused parameters are shown as ***undefined***. A ***parameter*** can be given a default value.

```
1 function showMessage(from, text = "no text given") {  
2     alert( from + ": " + text );  
3 }  
4  
5 showMessage("Ann"); // Ann: no text given
```

```
1 function showMessage(from, text) { // arguments: from, text  
2     alert(from + ': ' + text);  
3 }  
4  
5 showMessage('Ann', 'Hello!'); // Ann: Hello! (*)  
6 showMessage('Ann', "What's up?"); // Ann: What's up? (**)
```

# JavaScript – Functions

<https://javascript.info/function-basics>

A function can return a value at any point using **return**. It can also **return** without a value.

Never place return data on a separate line. JS assumes a **;** after **return**.

```
1 function checkAge(age) {  
2   if (age >= 18) {  
3     return true;  
4   } else {  
5     return confirm('Do you have permission from your parents?');  
6   }  
7 }  
8  
9 let age = prompt('How old are you?', 18);  
10  
11 if ( checkAge(age) ) {  
12   alert( 'Access granted' );  
13 } else {  
14   alert( 'Access denied' );  
15 }
```

```
1 function showMovie(age) {  
2   if ( !checkAge(age) ) {  
3     return;  
4   }  
5  
6   alert( "Showing you the movie" ); // (*)  
7   // ...  
8 }
```

# JavaScript – Function Expressions

<https://javascript.info/function-expressions>

In JavaScript, a function is a value. This code shows a *function expression*.

It's called as `sayHi()`, but it's still a value it can also be passed.

A *Function Expression* is created when program execution reaches its declaration, and it is usable only from that moment onward.

```
1 let sayHi = function() {  
2   alert( "Hello" );  
3 };
```

This *Function Declaration*:

(1) creates the function and puts it into a variable: `sayHi`.

(2) copies its reference into the variable `func`.

Now the function can be called as both `sayHi()` and `func()`.

```
1 function sayHi() { // (1) create  
2   alert( "Hello" );  
3 }  
4  
5 let func = sayHi; // (2) copy  
6  
7 func(); // Hello // (3) run the copy (it works)!  
8 sayHi(); // Hello // this still works too (why wouldn't it)
```

\*If there were parentheses after `sayHi`, `func = sayHi()` would write the result of the call `sayHi()` into `func`.

# Arrow Functions

<https://javascript.info/arrow-functions-basics>

Arrow Functions are a very simple and concise syntax for creating functions. Both the below expressions create a function that accepts arguments *arg1..argN*, then evaluates the expression and returns its result into *func*.

```
1 let func = function(arg1, arg2, ...argN) {  
2   return expression;  
3 };
```

Is the same as...

```
1 let func = (arg1, arg2, ...argN) => expression
```

This function accepts two arguments: a, b.  
It returns the result of **a + b**.

```
1 let sum = (a, b) => a + b;  
2  
3 /* This arrow function is a shorter form of:  
4  
5 let sum = function(a, b) {  
6   return a + b;  
7 };  
8 */  
9  
10 alert( sum(1, 2) ); // 3
```

```
1 let sayHi = () => alert("Hello!");
```

```
1 let double = n => n * 2;
```

With one argument, **()** are not required. With zero arguments empty **()** are required.

```
1 let sum = (a, b) => { // the curly brace opens a multiline function  
2   let result = a + b;  
3   return result; // if we use curly braces, then we need an explicit "return"  
4 };  
5  
6 alert( sum(1, 2) ); // 3
```

# JavaScript – Callback Functions

<https://javascript.info/function-expressions#callback-functions>  
<https://gist.github.com/ericelliott/414be9be82128443f6df>

Pass functions as values. (Line 15) The arguments `showOk()` and `showCancel()` of the call to `ask()` are called **callback functions**.

A function can be passed to be “called back” later (if necessary). `showOk()` becomes the callback for a “yes” answer, and `showCancel()` for a “no” answer.

```
1 function ask(question, yes, no) {
2   if (confirm(question)) yes()
3   else no();
4 }
5
6 function showOk() {
7   alert( "You agreed." );
8 }
9
10 function showCancel() {
11   alert( "You canceled the execution." );
12 }
13
14 // usage: functions showOk, showCancel are passed as arguments to ask
15 ask("Do you agree?", showOk, showCancel);
```

We can use **Function Expressions** to write the same function, but much shorter. These are called **Anonymous Functions** and are very common. They are also referred to as Lambda Functions.

```
1 function ask(question, yes, no) {
2   if (confirm(question)) yes()
3   else no();
4 }
5
6 ask(
7   "Do you agree?",
8   function() { alert("You agreed."); },
9   function() { alert("You canceled the execution."); }
10 );
```

# IIFE - Immediately Invoked Function Expression

<https://developer.mozilla.org/en-US/docs/Glossary/IIFE>

[https://en.wikipedia.org/wiki/Immediately\\_invoked\\_function\\_expression](https://en.wikipedia.org/wiki/Immediately_invoked_function_expression)

An **IIFE** (*Immediately Invoked Function Expression*) (pronounced “iffy”) is a **JavaScript** function that runs as soon as it is defined. It’s also known as a Self-Executing Anonymous Function

**IIFE** functions contain two major parts:

- The first is the anonymous function with lexical scope enclosed within the Grouping Operator **()**. This prevents accessing variables within the **IIFE** idiom as well as polluting the global scope.
- The second part creates the immediately invoked function expression **()** through which the JavaScript engine will directly interpret the function.

```
1  (function () {  
2      statements  
3  })();
```

```
1  (function() {  
2      alert("I am not an IIFE yet!");  
3  });
```

```
1  // Variation 1  
2  (function() {  
3      alert("I am an IIFE!");  
4  }());
```

# IIFE

## Immediately Invoked Function Expression

<https://developer.mozilla.org/en-US/docs/Glossary/IIFE>

[https://en.wikipedia.org/wiki/Immediately\\_invoked\\_function\\_expression](https://en.wikipedia.org/wiki/Immediately_invoked_function_expression)

---

Any variable declared within the expression cannot be accessed from outside it.

Assigning an *IIFE* to a variable stores the function's return value, not the function definition itself.

```
1 | (function () {  
2 |     var aName = "Barry";  
3 | })();  
4 | // Variable aName is not accessible from the outside scope  
5 | aName // throws "Uncaught ReferenceError: aName is not defined"
```

```
1 | var result = (function () {  
2 |     var name = "Barry";  
3 |     return name;  
4 | })();  
5 | // Immediately creates the output:  
6 | result; // "Barry"
```

# Scope with Nested Functions (and Closure)

<https://javascript.info/closure>

If a variable is declared inside a code block {...}, it's only visible inside that block.

A nested function can access variables declared inside it's code block and inside it's parent code block.

A nested function can be returned (as a property of a new object or as a result by itself). It can then be used anywhere else and it will still have access to the same outer variables.

```
1 function sayHiBye(firstName, lastName) {  
2  
3     // helper nested function to use below  
4     function getFullName() {  
5         return firstName + " " + lastName;  
6     }  
7  
8     alert( "Hello, " + getFullName() );  
9     alert( "Bye, " + getFullName() );  
10  
11 }
```

```
1 function makeCounter() {  
2     let count = 0;  
3  
4     return function() {  
5         return count++;  
6     };  
7 }  
8  
9 let counter = makeCounter();  
10  
11 alert( counter() ); // 0  
12 alert( counter() ); // 1  
13 alert( counter() ); // 2
```

# Scope and Closure

<https://developer.mozilla.org/en-US/docs/Web/JavaScript/Closures>

---

A ***closure*** is a ***function*** enclosed with references to its surrounding state (the ***lexical environment***). A ***closure*** gives access to an outer ***function's*** scope from an inner ***function***.

```
1 function init() {  
2     var name = 'Mozilla'; // name is a local variable created by init  
3     function displayName() { // displayName() is the inner function, a closure  
4         alert(name); // use variable declared in the parent function  
5     }  
6     displayName();  
7 }  
8 init();
```

`init()` creates local variable (`name`) and a function, `displayName()`. `displayName()` is an inner function ***defined*** inside `init()`. It's available only within the body of `init()`. `displayName()` has no local variables.

Because inner functions have access to outer function variables, `displayName()` accesses the ***name*** variable declared in its parent function, `init()`. This is Lexical Scoping.

# Scope and Closure Example

<https://developer.mozilla.org/en-US/docs/Web/JavaScript/Closures>

---

**makeAdder(x)** takes a single argument, x, and **returns** a new function.

The returned function takes a single argument y and returns (x + y).

**add5** and **add10** are both **closures**.

They share the same function body definition but store different lexical environments.

In **add5**'s lexical environment, x is 5, while in **add10**'s, x is 10.

```
1  function makeAdder(x) {  
2      return function(y) {  
3          return x + y;  
4      };  
5  }  
6  
7  var add5 = makeAdder(5);  
8  var add10 = makeAdder(10);  
9  
10 console.log(add5(2)); // 7  
11 console.log(add10(2)); // 12
```

# Try/Catch/Finally

<https://javascript.info/try-catch#the-try-catch-syntax>

The JS *Try/Catch* block works similarly to the C# *Try/Catch* Block. There is only one 'error' object generated. The 'error' object has three parts

- Name – the Error Name, Like “Reference Error”.
- Message – a text message with error details
- Stack – a stack trace of the calls that led to the error.

JavaScript has many built-in, standard errors: *Error*, *SyntaxError*, *ReferenceError*, *TypeError* and others.

The *Finally* Block always executes.

```
1 let error = new Error(message);
2 // or
3 let error = new SyntaxError(message);
4 let error = new ReferenceError(message);
5 // ...
```

```
1 try {
2
3   alert('Start of try runs'); // (1) <--
4
5   lalala; // error, variable is not defined!
6
7   alert('End of try (never reached)'); // (2)
8 } catch(err) {
9
10  alert(`Error has occurred!`); // (3) <--
11
12 }
13 }
```

```
1 let json = '{ "age": 30 }'; // incomplete data
2
3 try {
4
5   let user = JSON.parse(json); // <-- no errors
6
7   if (!user.name) {
8     throw new SyntaxError("Incomplete data: no name"); // (*)
9   }
10
11   alert( user.name );
12 } catch(e) {
13   alert( "JSON Error: " + e.message ); // JSON Error: Incomplete data
14 }
15 }
```
