

Containerization and Docker Fundamentals

.NET CORE

*Docker provides the ability to run one or more applications, in an isolated environment called a **Container**, without a hypervisor, on a single computer.*

[HTTPS://DOCS.DOCKER.COM/ENGINE/DOCKER-OVERVIEW/](https://docs.docker.com/engine/docker-overview/)

What is Containerization?

<https://hackernoon.com/what-is-containerization-83ae53a709a6>

Containerization involves bundling an application together with all the configuration files, libraries, and dependencies required for it to run efficiently and bug-free across different computing environments.

The most popular **containerization** ecosystems are **Docker** and **Kubernetes**.

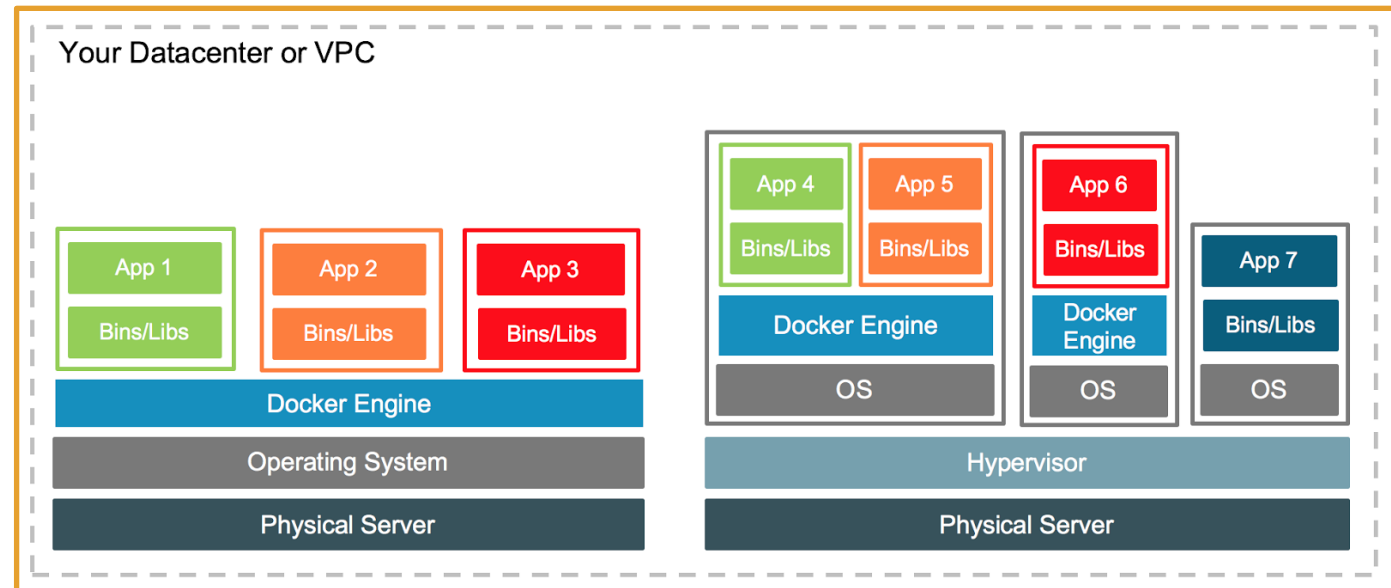

What is Virtualization?

https://en.wikipedia.org/wiki/Virtualization#Hardware_virtualization
<https://www.docker.com/blog/containers-and-vms-together/>

Hardware or platform **virtualization** refers to the creation of a Virtual Machine (an application) that simulates a real computer within an existing operating system.

Software executed on a Virtual Machine is isolated from the underlying hardware resources.

Examples of Virtualization Software.

<https://en.wikipedia.org/wiki/Virtualization>

V · T · E		Virtualization software		[hide]
Comparison of platform virtualization software				
Hardware virtualization (hypervisors)	Native	Adeos · CP/CMS · Hyper-V · KVM (Red Hat Enterprise Virtualization) · LDomS / Oracle VM Server for SPARC · Logical Partition (LPAR) · LynxSecure · PikeOS · Proxmox VE · SIMMON · VMware ESXi (VMware vSphere · vCloud) · VMware Infrastructure · Xen (Oracle VM Server for x86 · XenServer) · XtratuM · z/VM

Docker – Purpose

<https://docs.docker.com/engine/docker-overview/#what-can-i-use-docker-for>

Docker allows developers to work in standardized environments using **Containers** which provide applications and services.

Containers are perfect for **CI/CD** workflows.

1. Developers write code locally in a **development environment** and share their work using **Docker containers**.
2. They can use Docker to push their applications into a test environment to execute automated and manual tests.
3. Bugs can be fixed in the **development environment** and redeployed to the **test environment** for re-testing and validation.
4. When testing is complete, developers push the updated image to the **production environment**.

Docker – Benefits

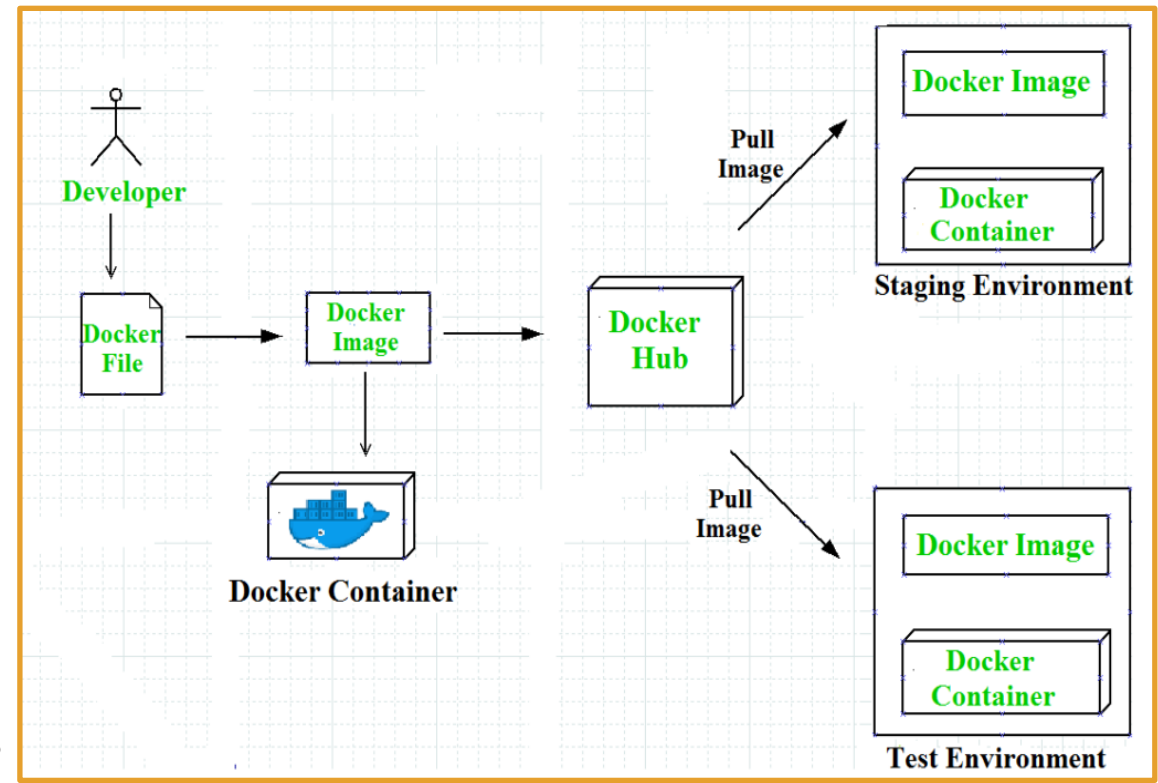

<https://docs.docker.com/engine/docker-overview/#what-can-i-use-docker-for>

Responsive deployment and scaling:

- **Docker Containers** are portable. They can run on a local laptop, on physical and virtual machines, in a data center, or on cloud providers.
- You can scale up or tear down applications (and services) as business needs dictate.

Run more workloads on the same hardware:

- Docker is lightweight and fast.
- Docker is NOT a Virtual Machine.
 - a *virtual machine* (VM) runs a full-blown “guest” operating system with *virtual* access to host resources through a hypervisor. VMs incur a lot of overhead.

The Docker Platform

<https://www.docker.com/resources/what-container>

Docker provides a platform to manage the entire lifecycle of your **containers**:

1. You develop an application and its supporting components using a **Container**.
2. The **Container** becomes the unit for distributing and testing your application.
3. Deploy your application into your production environment as a **Container**.
4. This process is identical for all production environments:
 - in a local data center,
 - a cloud provider,
 - or a hybrid.

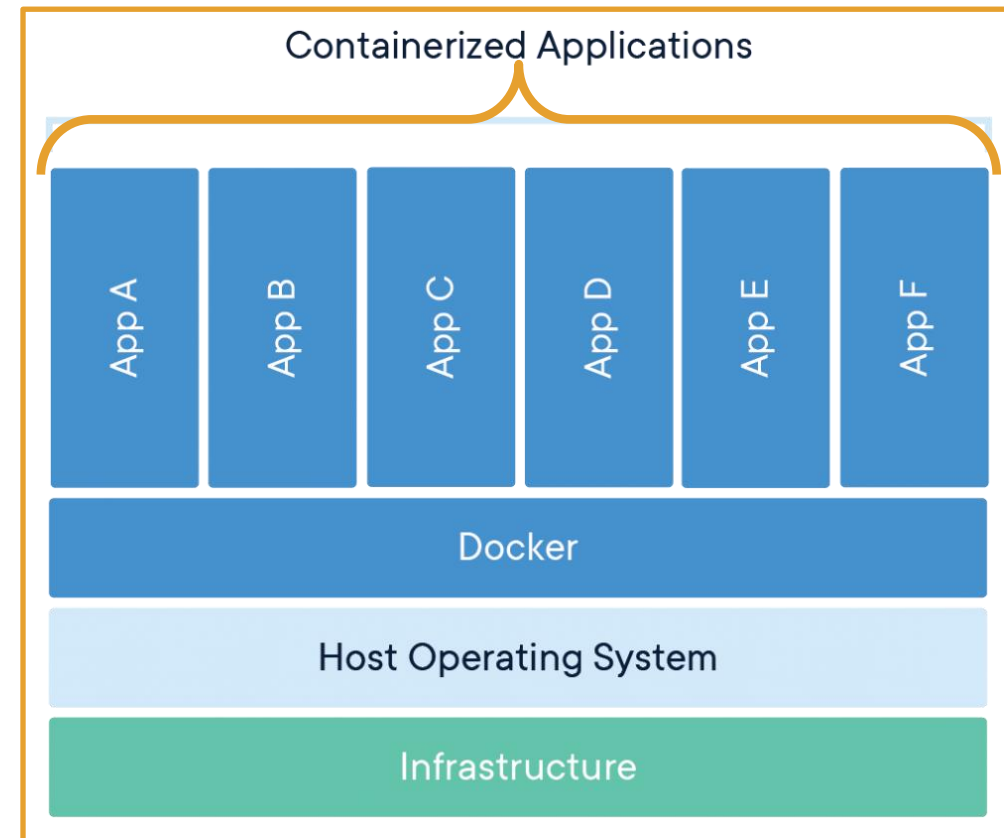

Docker Container

<https://www.docker.com/resources/what-container>
<https://docs.docker.com/get-started/>

A **Docker Image** is a standalone executable package that includes everything needed to run an application: code, runtime, system tools and libraries, and settings.

Docker Images become **Docker Containers** at runtime when run on the **Docker Engine**. **Containers** run identically on different machines (Linux or PC).

A **container** is a running process with encapsulation features applied to it to keep it isolated from the host. Each **Container** interacts with its own private filesystem provided by a **Docker image**.

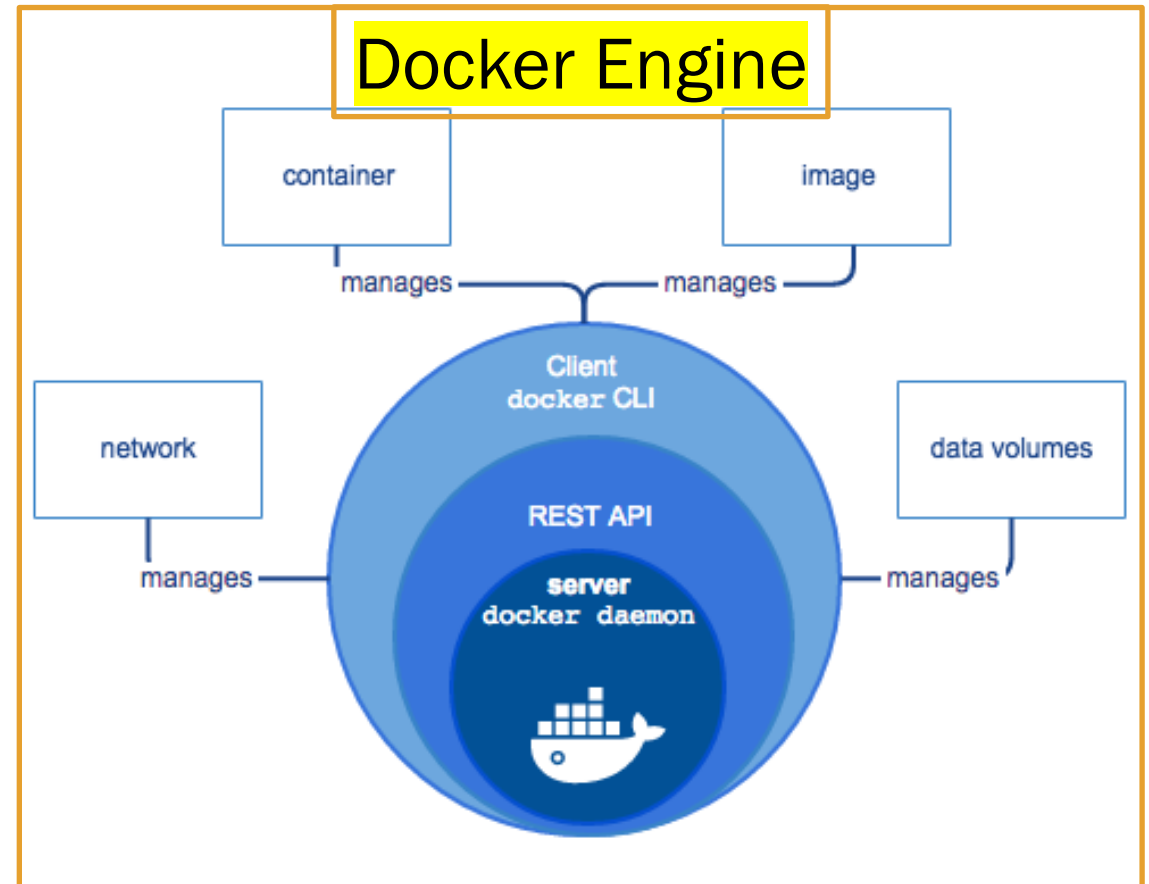

Docker Engine

<https://docs.docker.com/engine/docker-overview/#docker-engine>

Docker Engine is a client-server application with three major components:

1. A server, which is a long-running program called a **daemon**.
2. A **REST API** which specifies interfaces that programs can use to talk to the daemon and instruct it what to do. You interact with the **daemon** with the **dockerd** command.
3. A command line interface (**CLI**) client (**docker** [command]).

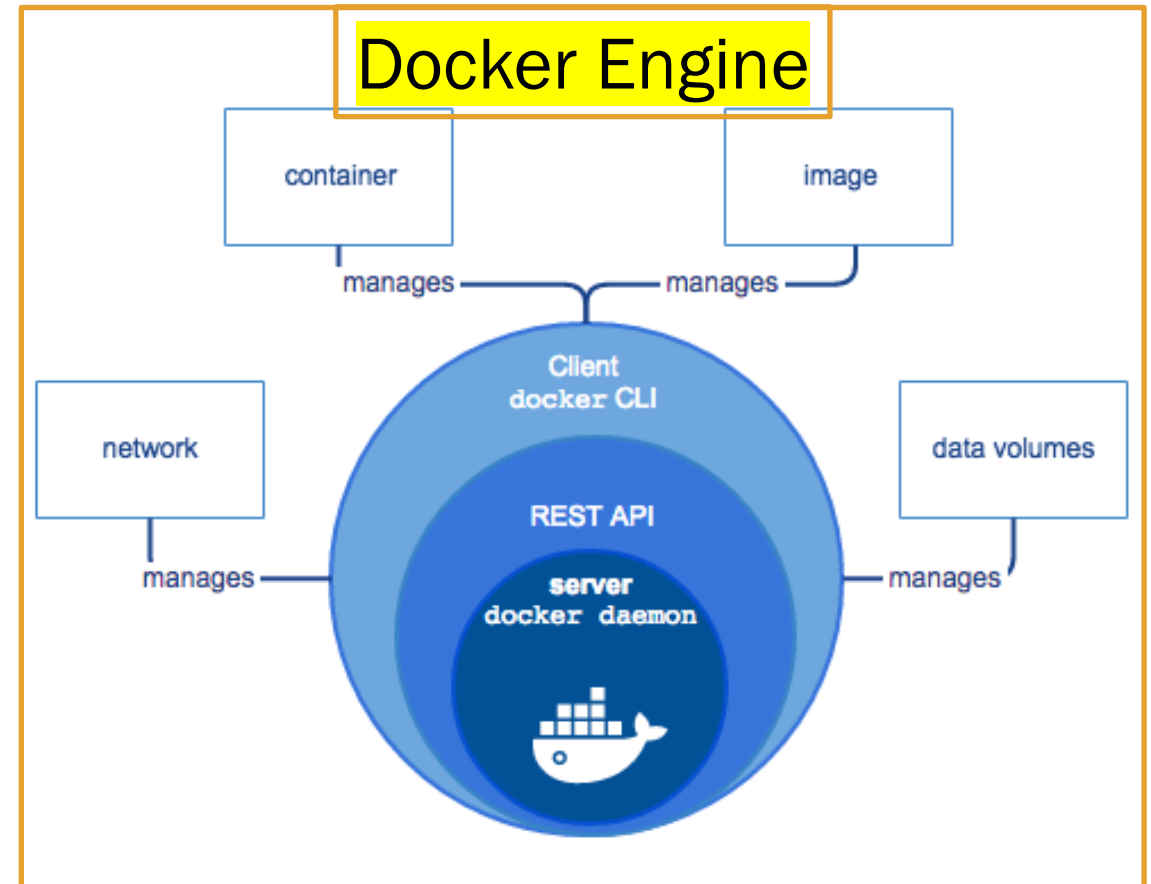

Docker Engine

<https://docs.docker.com/engine/docker-overview/#docker-engine>

The Docker *CLI* uses the *Docker REST API* to interact with the *Docker daemon* through scripting and/or *CLI* commands. Many other Docker applications use the underlying *API* and *CLI*.

The *daemon* creates and manages Docker objects, such as *images*, *Containers*, networks, and *volumes*.

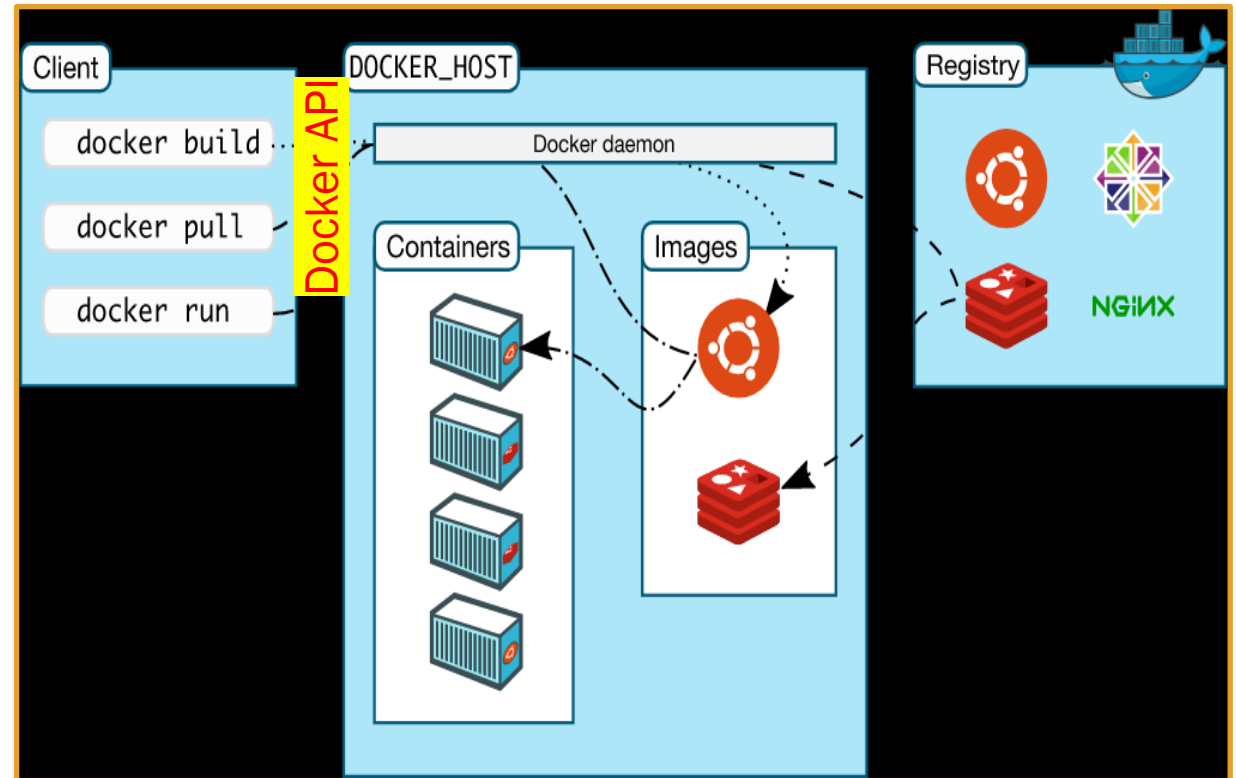

Docker Architecture

<https://docs.docker.com/engine/docker-overview/#docker-architecture>

Docker uses a *client-server architecture*. The *Docker client* talks to the *Docker daemon (server)*, which builds, runs, and distributes *Docker containers*.

The *Docker client* and *daemon* can run on the same system, or you can connect a *Docker client* to a remote *Docker daemon*.

The *Docker client* and *daemon* communicate using a *REST API*.

Docker Client

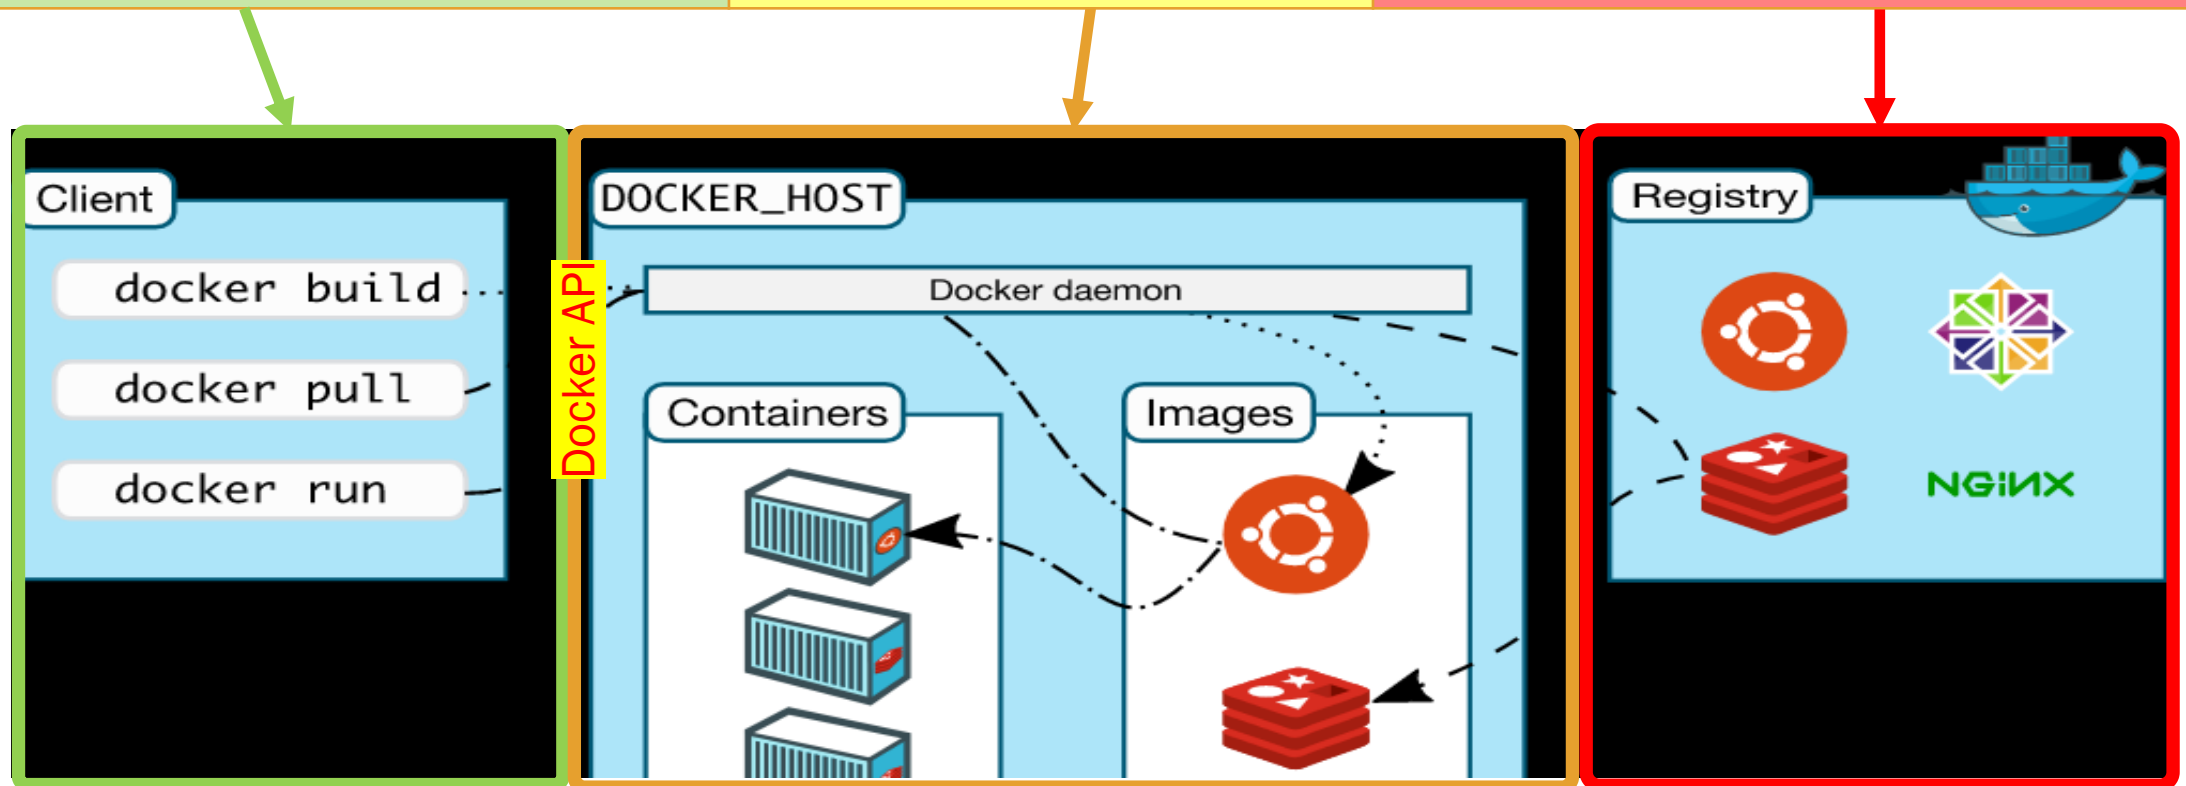

The *Docker client* is the primary way that most Docker users interact with Docker. With *docker run*, the client sends commands to *dockerd*, which carries them out. The *docker* keyword specifies the *Docker API*.

Docker daemon

The *Docker daemon* (*dockerd*) listens for *Docker API* requests and manages Docker objects such as *images*, *networks*, *containers*, and *volumes*.

Docker registries

A Docker registry stores Docker images. Docker Hub is a public registry. With the *docker pull* or *docker run* commands, images are pulled from the configured registry. When you use the *docker push* command, the image is pushed to the configured registry.

Docker Container and Docker Image

<https://docs.docker.com/engine/docker-overview/#docker-architecture>

A **container** is a runnable instance of an **image**. You can create, start, stop, move, or delete a **container** using the **Docker API** or **CLI**.

You can connect a **container** to one or more networks, attach storage to it, or even create a new **image** based on its current state.

A **Container** is defined by an **image** as well as any configuration options you provide to it when you create or start it.

An **image** is a read-only template with instructions for creating a **Docker container**.

An **image** can even be based on another **image**. An **image** could be based on one **image** but install a different web server, then install an application and the configuration details needed to make the application run.

To build an **image**, create a **Dockerfile** which defines the steps to create an **image** and run it.

When you change a **Dockerfile** and rebuild the **image**, only those layers which have changed are rebuilt.

List of Basic Docker commands

Command	Purpose
<code>docker start [containername]</code>	Start a container.
<code>docker images</code>	List images installed
docker container [command]	Manage containers
<code>docker stop [containername]</code>	Stop a running container
<code>docker image ls</code>	list the images downloaded to your machine.
<code>docker ps --a</code>	Lists all containers
docker run [containername]	Re-run a container
<code>docker build -t myimage -f dockerfile .</code>	Build an image called myimage from a Dockerfile
<code>docker rm [containername]</code>	Delete a container
docker push [imagename]	Push an image to your repo in the Docker Registry
<code>docker create myimage</code>	Create a container from an image
<code>docker ps</code>	Show running containers
<code>docker attach [containername]</code>	Connect to a running container

Docker – Setup and Test a Container

<https://docs.docker.com/get-started/>

- 1. Download Docker Desktop.
- 2. Go to Docker.com and create an account
- 3. Run ***docker --version*** in the Command Line to see what Docker version you have.
- 4. Run ***docker run hello-world*** to test that docker is running correctly. You don't have this image so it will get downloaded automatically and run.
- 5. Run ***docker image ls*** to list the downloaded hello-world image on your machine.
- 6. Run ***docker ps -all*** to see the container created from the *hello-world image*.
- 7. Do the Docker tutorial [here](#).
- 8. Then complete the [Getting Started Walk-through for Developers](#) tutorial.

Docker in action

The following command runs an ubuntu container, attaches interactively to your local command-line session, and runs the `/bin/bash` script.

```
$ docker run -i -t ubuntu /bin/bash
```

The following happens (assuming default registry configuration):

1. If you do not have the **ubuntu** image locally, Docker pulls it from your configured registry, as though you had run **docker pull ubuntu** manually.
2. Docker creates a new container, as though you had run a **docker container create** command manually.
3. Docker allocates a read-write filesystem to the container, as its final layer.
 - This allows a running container to create or modify files and directories in its local filesystem.
4. Docker creates a network interface to connect the container to the default network,
 - because you did not specify any networking options.
 - This includes assigning an IP address to the container.
 - By default, containers can connect to external networks using the host machine's network connection.
5. Docker starts the container and executes **/bin/bash**.
 - Because the container is running interactively and attached to your terminal (due to the **-i** and **-t** flags), you can provide input using your keyboard while the output is logged to your terminal.
6. When you type **exit** to terminate the **/bin/bash** command, the container stops but is not removed.
 - You can start it again or remove it.

Assignment 2

The assignment for after finishing the tutorials is to redo this tutorial with modifications.

The modifications are:

- you will run it on your local machine and
- make the necessary changes to get it to work.

You don't have the .html and .png files that are ***COPY***d into the container in the Dockerfile. There are certainly others things missing and it is your task to find out what must be changed and change them.

The first person who finishes and presents to the class tomorrow morning will get 5 points added to their quiz on Monday.

You must be the first to contact me with a working site and explanation of exactly what had to be changed.

Next Steps...

Now you can move on to creating your own
Dockerfiles, Images, and Containers!
